DEVELOPER GUIDE

Java Clean Code Principles

A practical guide to writing clean, maintainable Java — covering foundational practices and modern Java features. 2026 Edition.

CONTENTS

01 Naming: Be Precise, Follow Conventions

02 Short Methods & Single Responsibility

03 Comments: Explain Why, Not What

04 Eliminate Magic Numbers and Strings

05 Exception Handling: Be Specific, Fail Fast

06 Streams & Lambdas: Readable Over Clever

07 Testing: Untested Code Isn't Clean Code

08 Simplicity Over Cleverness (YAGNI)

09 Dependency Injection & Composition

10 Refactor Continuously (With Tests)

11 Embrace Modern Java Features

12 Immutability by Default

13 Optional: Use Idiomatically

14 Structured Logging Over System.out

15 Null Safety Strategy

++ Quick Reference Table

01 Naming: Be Precise, Not Just Descriptive

Consistent, descriptive naming is foundational. But the real trap isn't cryptic abbreviations — it's names that *seem* descriptive but are actually vague.

Avoid vague "manager" and "data" names

```java
// Bad — what does "process" mean? What "data"?
public class DataManager {
    public void processData(List<String> data) { ... }
}

// Good — says exactly what it does
public class InvoiceExporter {
    public void exportToCsv(List<Invoice> invoices) { ... }
}
```

Booleans should read like a yes/no question

```java
// Bad
boolean status;
boolean flag;

// Good
boolean isActive;
boolean hasExpired;
boolean canRetry;
```

Avoid abbreviations unless universally understood

```java
// Bad
int empCnt;
String txnId;

// Good
int employeeCount;
String transactionId;
```

Java naming conventions (camelCase & friends)

Java has well-established casing rules. Breaking them confuses every developer who reads your code and breaks IDE tooling.

Java — Naming Conventions

```java
// Classes & interfaces — PascalCase (UpperCamelCase)
public class OrderService { }
public interface PaymentGateway { }
public record TradeExecution(...) { }
public sealed interface TradeResult { }

// Methods & variables — camelCase (lowerCamelCase)
public void calculateTotalPrice() { }
int itemCount = 0;
String customerEmail;

// Constants — SCREAMING_SNAKE_CASE
private static final int MAX_RETRY_COUNT = 3;
private static final String DEFAULT_CURRENCY = "USD";

// Packages — all lowercase, no underscores
// com.example.invoice.service
// com.example.trade.execution

// Enums — PascalCase type, SCREAMING_SNAKE_CASE values
public enum OrderStatus {
    PENDING, PROCESSING, COMPLETED, CANCELLED
}

// Type parameters — single uppercase letter (or short word)
public class Repository<T, ID> { }
public interface Converter<S, T> { }
```

Common naming pitfalls

- **Inconsistent acronyms** — use `HttpClient` and `parseJson`, not `HTTPClient` or `parseJSON`. Treat acronyms as words in camelCase.
- **Hungarian notation** — don't prefix types like `strName` or `iCount`. The type system already tells you this.

- **Meaningless suffixes** — `UserData`, `UserInfo`, `UserObject` all say the same thing. Pick one and be consistent.
- **Verb vs noun confusion** — classes are nouns (`InvoiceExporter`), methods are verbs (`exportInvoice`). Don't name a class `ExportInvoices` or a method `invoice`.

> **Rule of thumb:** If you have to read the method body to understand what a name means, the name is wrong. Good names make the code read like a story — `orderService.validateAndSubmit(order)` tells you everything without opening the file.

02 Short Methods & Single Responsibility

Every method should do one thing. If it doesn't fit on your screen (~20–25 lines), it's probably doing too much.

Before — one method doing three jobs

```java
public void handleOrder(Order order) {
    if (order == null || order.getItems().isEmpty()) {
        throw new IllegalArgumentException("Invalid order");
    }
    double total = 0;
    for (Item item : order.getItems()) {
        total += item.getPrice() * item.getQuantity();
    }
    if (order.getCustomer().isPremium()) {
        total *= 0.9;
    }
    paymentService.processPayment(
        new Payment(order.getCustomer(), total));
}
```

After — each concern is isolated and testable

```java
public void handleOrder(Order order) {
    validateOrder(order);
    double total = calculateOrderTotal(order);
    executePayment(order.getCustomer(), total);
}
```

03 Comments: Explain *Why*, Not *What*

If you need a comment to explain what code does, that's a signal to rename or extract a method. Reserve comments for things code structurally *cannot* express.

Comments that should be refactored away

Java

```java
// Bad — the comment IS the method name you should have written
// Check if the user is eligible for a discount
if (user.getAge() > 18 && user.getOrders().size() > 5
    && user.isPremiumMember()) {
    applyDiscount(order);
}

// Good — extract the condition
if (user.isEligibleForDiscount()) {
    applyDiscount(order);
}
```

Java

```java
// Bad — narrates the obvious
// Create a new user
User user = new User();
// Set the name
user.setName("Tom");
// Save the user
userRepository.save(user);
```

Comments that ARE valuable — explaining *why*

Java — Business context

```java
// FX rates from the ECB feed are delayed by ~15 minutes,
// so we add a buffer margin to protect against stale quotes
private static final double FX_RATE_BUFFER = 0.02;
```

Java — Non-obvious constraint

```java
// The payment gateway rejects amounts below 0.50 USD
// due to processing fees, so we bundle micro-transactions
if (pendingAmount < MINIMUM_CHARGE_THRESHOLD) {
    batchQueue.add(transaction);
    return;
}
```

Java — Deliberate tradeoff

```java
// ArrayList over LinkedList: profiling showed cache locality
// gives 3x throughput on typical datasets (< 10k elements)
private final List<Trade> activeTrades = new ArrayList<>();
```

Records as self-documenting code

Java 16+

```java
// 40+ lines of POJO boilerplate becomes:
public record DiscountResult(
    double originalPrice,
    double discountRate,
    double finalPrice
) {}
```

> **Rule of thumb:** Before writing a comment, ask: *"Can I rename something, extract a method, or restructure the code so this comment becomes redundant?"* If yes, do that. Comments are for: business context, external constraints, historical reasons, and performance justifications.

04 Eliminate Magic Numbers and Strings

Unnamed constants make code unreadable and fragile. Use named constants, enums, or sealed interfaces.

Java

```java
// Bad — what does 0.1 represent?
return price * 0.1;

// Good — named constant
private static final double STANDARD_DISCOUNT_RATE = 0.10;
return price * STANDARD_DISCOUNT_RATE;
```

Sealed interfaces when behavior varies per type

Java 17+

```java
public sealed interface PaymentMethod
    permits CreditCard, BankTransfer, Crypto {
    BigDecimal calculateFee(BigDecimal amount);
}

public record CreditCard(String last4)
    implements PaymentMethod {
    public BigDecimal calculateFee(BigDecimal amount) {
        return amount.multiply(new BigDecimal("0.029"));
    }
}
```

05 Exception Handling: Be Specific, Fail Fast

Catch specific exceptions. Never catch generic `Exception`. Provide context that helps debugging.

Java

```java
// Bad — swallows everything
try { userService.registerUser(user); }
catch (Exception e) {
    System.out.println("An error occurred.");
}

// Good — specific catches
try {
    userService.registerUser(user);
} catch (UserAlreadyExistsException e) {
    log.warn("Duplicate registration: {}",
        user.getEmail());
    return ResponseEntity.conflict()
        .body("User already exists");
} catch (DatabaseConnectionException e) {
    log.error("DB failure: {}", e.getMessage(), e);
    throw new ServiceUnavailableException(
        "Cannot process request", e);
}
```

- Always use `try-with-resources` for `Closeable` / `AutoCloseable` resources
- In Spring Boot, centralize with `@ControllerAdvice`
- Never use exceptions for control flow
- Fail fast — validate inputs at the boundary, not deep in the call stack

06 Streams & Lambdas: Readable Over Clever

Method references are preferred for simple mappings. Break complex chains into named predicates.

Java

```java
// Clean and readable
List<String> activeUserNames = users.stream()
    .filter(User::isEnabled)
    .map(User::getName)
    .sorted()
    .toList(); // Java 16+ preferred

// Complex logic — extract predicates
Predicate<Order> isHighValueCompleted = order ->
    order.getStatus() == COMPLETED
    && order.getTotal().compareTo(threshold) > 0;

var result = orders.stream()
    .filter(isHighValueCompleted)
    .flatMap(order -> order.getItems().stream())
    .toList();
```

When NOT to use streams: If you need indexes, early `break`, mutable accumulators, or checked exceptions — a `for` loop is cleaner.

07 Testing: Untested Code Isn't Clean Code

Tests are not a separate concern from clean code — they enable it. You can't safely refactor without them.

Java — JUnit 5 + AssertJ

```java
@Test
@DisplayName("Should apply 10% discount for premium")
void shouldApply10PercentDiscount_whenPremium() {
    var calc = new DiscountCalculator();
    double result = calc.computeDiscount(100.0, 0.10);
    assertThat(result).isCloseTo(10.0, within(0.001));
}

@ParameterizedTest
@CsvSource({
    "100.0, 0.10, 10.0",
    "50.0,  0.00, 0.0",
    "200.0, 0.25, 50.0"
})
void shouldComputeDiscountCorrectly(
    double price, double rate, double expected) {
    assertThat(calc.computeDiscount(price, rate))
        .isCloseTo(expected, within(0.001));
}
```

Follow Arrange-Act-Assert

Java

```java
@Test
void shouldRejectExpiredCoupon() {
    // Arrange
    var coupon = new Coupon("SAVE10",
        LocalDate.of(2025, 1, 1));
    var order = new Order(BigDecimal.valueOf(100));

    // Act & Assert
    assertThatThrownBy(() -> order.applyCoupon(coupon))
        .isInstanceOf(ExpiredCouponException.class)
        .hasMessageContaining("SAVE10");
}
```

08 Simplicity Over Cleverness (YAGNI)

Don't build abstractions you don't need yet. Extract an abstraction when you have **three** concrete cases, not before.

```java
// Over-engineered — nobody needs this
Function<Double, Function<Integer, Double>> calculate = p -> q -> p * q;

// Just write this
public double computeOrderAmount(double price, int quantity) {
    return price * quantity;
}
```

More realistic over-engineering to avoid

- Creating `AbstractDiscountStrategyFactory` when you have one discount type
- Building a plugin system when you have two implementations
- Using the Strategy pattern for a two-branch `if` / `else`

09 Dependency Injection & Composition

Inject dependencies through constructors. Code to interfaces. Prefer composition over inheritance.

Java

```java
// Bad — tight coupling, untestable
public class OrderService {
    private PaymentService ps = new PaymentService();
}

// Good — injectable, testable, swappable
public class OrderService {
    private final PaymentGateway paymentGateway;

    public OrderService(PaymentGateway paymentGateway) {
        this.paymentGateway = paymentGateway;
    }
}
```

> **Note:** Since Spring 4.3+, single-constructor classes don't need `@Autowired`. The principle applies even without Spring.

Composition over inheritance

Java — Fragile inheritance

```java
// Fragile inheritance hierarchy
class Animal { }
class FlyingAnimal extends Animal { void fly() { } }
class SwimmingFlyingAnimal extends FlyingAnimal { void swim() { } } // uh oh
```

Java — Composition via interfaces

```java
interface Flyer { default void fly() { /* ... */ } }
interface Swimmer { default void swim() { /* ... */ } }

class Duck implements Flyer, Swimmer { }
```

10 Refactor Continuously (With Tests)

Refactoring without tests is just moving code around and hoping. The cycle is: write tests → refactor → verify tests still pass.

- **Extract Method** — pull a block into a named method
- **Introduce Parameter Object** — replace 3+ related parameters with a record
- **Replace conditional with polymorphism** — sealed interfaces + pattern matching
- **Inline trivial methods** — if a method just delegates, remove the indirection

11 Embrace Modern Java Features

These aren't optional syntax sugar — they eliminate entire categories of code smells.

Records (Java 16+)

Java 16+

```java
public record TradeExecution(
    String symbol,
    BigDecimal price,
    int quantity,
    Instant executedAt
) {
    public TradeExecution {
        Objects.requireNonNull(symbol);
        if (quantity <= 0)
            throw new IllegalArgumentException(
                "Quantity must be positive");
    }
}
```

Sealed Classes (Java 17+)

Java 17+

```java
public sealed interface TradeResult
    permits Success, Failure, Pending {
    record Success(TradeExecution exec)
        implements TradeResult {}
    record Failure(String reason, Exception cause)
        implements TradeResult {}
    record Pending(String orderId)
        implements TradeResult {}
}
```

Pattern Matching in Switch (Java 21+)

Java 21+

```java
public String describe(TradeResult result) {
    return switch (result) {
        case Success s -> "Executed %s shares of %s"
            .formatted(s.exec().quantity(),
                       s.exec().symbol());
        case Failure f -> "Failed: " + f.reason();
        case Pending p -> "Pending: " + p.orderId();
    };
}
```

Text Blocks (Java 15+)

Java 15+

```java
String query = """
    SELECT symbol, price, quantity
    FROM trades
    WHERE executed_at > :since
      AND status = 'COMPLETED'
    ORDER BY executed_at DESC
    """;
```

`var` for Local Type Inference (Java 10+)

Java 10+

```java
// Good — type is obvious from the right side
var users = userRepository.findAllActive();
var mapper = new ObjectMapper();

// Bad — type is not obvious, use explicit type
var result = service.process(data); // What type is result?
```

12 Immutability by Default

Mutable state is the root of countless bugs. Default to immutable and opt into mutability only when needed.

Java

```java
// Use records for data
public record Money(BigDecimal amount, Currency currency) {}

// Use unmodifiable collections
List<String> symbols = List.of("AAPL", "GOOG", "MSFT");
Map<String, Integer> counts = Map.of(
    "trades", 42, "errors", 0);

// Mark fields final
private final List<Order> orders;
```

13 Optional: Use Idiomatically

`Optional` is for return types that may have no value. Not for fields, not for parameters.

Java

```java
// Bad — imperative Optional usage
Optional<User> user = findUser(id);
if (user.isPresent()) {
    return user.get().getName();
}

// Good — chain operations
return findUser(id)
    .map(User::getName)
    .orElse("Unknown");

// Good — throw when absence is a bug
User user = findUser(id)
    .orElseThrow(() ->
        new UserNotFoundException(
            "No user with id: " + id));

// Never do these:
private Optional<String> name;           // field
public void setName(Optional<String> n)  // param
```

14 Structured Logging Over System.out

`System.out.println` has no place in production code. Use structured logging with SLF4J.

```java
// Bad
System.out.println("Order processed!");

// Good — structured, leveled, searchable
log.info("Order processed: orderId={}, total={}",
    order.getId(), total);

log.error("Payment failed: orderId={}",
    orderId, exception);
```

Use MDC (Mapped Diagnostic Context) for request-scoped context like correlation IDs, user IDs, and session identifiers.

15 Null Safety Strategy

Design APIs that never return null. Use annotations to make intent explicit.

Java

```java
// Never return null — return empty collections
public @NonNull List<Trade> findTrades(
    @NonNull String symbol) {
    return trades.getOrDefault(symbol, List.of());
}

// Use Optional for genuinely optional values
public Optional<User> findByEmail(String email) {
    // ...
}

// Validate at boundaries
public void createOrder(
    @NonNull Customer customer,
    @NonNull List<Item> items) {
    Objects.requireNonNull(customer);
    Objects.requireNonNull(items);
    // safe to proceed without null checks
}
```

++ Quick Reference

PRINCIPLE	ONE-LINER
Naming	Be Precise, Follow Conventions
Short methods	One job, ~20 lines max, testable in isolation
Comments	Explain *why*, not *what* — or refactor instead
No magic values	Named constants, enums, sealed types
Exceptions	Specific catches, fail fast, centralize in Spring
Streams	Readable over clever; extract complex predicates
Testing	Untested code isn't clean; AAA pattern; parameterized tests
YAGNI	Extract abstractions at three cases, not one
DI & composition	Constructor injection; interfaces over inheritance
Refactor	Continuously, but only with test coverage
Modern Java	Records, sealed classes, pattern matching, text blocks
Immutability	Default to final, records, unmodifiable collections
Optional	Return types only; map/flatMap/orElseThrow
Logging	SLF4J + MDC, never System.out
Null safety	@NonNull, empty collections, validate at boundaries
